Abstract. Karyotypes of eight Psocoptera species are reported for the first time. In *Venezuela oyamai* (Enderlein, 1906) (Caeciliusidae), *Peripsocus golubae* Lienhard, 2006 (Peripsocidae), *Trichopsocus dalii* (McLachlan, 1867) (Trichopsocidae), *Hemineura dispar* Tetens, 1891 (Elipsocidae), and *Amphigerontia contaminata* (Stephens, 1836) (Psocidae) $2n = 16 + XX/X0$. In *Elipsocus moebiusi* Tetens, 1891 (Elipsocidae) $2n = 12 + XX/X0$. *Neopsocopsis hitricornis* (Reuter, 1893) (Psocidae) has $2n = 14 + XX/X0$, and *Kolbia quisquiliarum* Bertkau, 1883 (Amphipsocidae) has $2n = 14 + \text{neo-XY}/XX$. In addition, three seminal follicles per testis have been established in *V. oyamai*, *H. dispar*, *A. contaminata*, and *N. hitricornis* and one follicle in *P. golubae* and *T. dalii*. All the data available on psocopteran karyotypes are tabulated and shortly reviewed.

Key words: Psocoptera, karyotype, chromosome number, chromosomal mechanism of sex determination.

INTRODUCTION

Psocoptera are a hemimetabolous insect order, belonging with the orders Phthiraptera, Thysanoptera, Heteroptera, and Homoptera to the Cohort Paraneoptera. Within Psocoptera three suborders, Trogiomorpha, Troctomorpha, and Psocomorpha, have been accepted (Lienhard, 1998; Lienhard, Smithers, 2002).

Chromosome systems of Psocoptera are still not adequately explored, although some papers concerning psocopteran karyotypes have been published recently (Nokkala, Golub, 2002, 2006; Golub, 2004). Like the other Paraneoptera, the species of Psocoptera have holocentric chromosomes. So far, chromosome numbers have been established for 82 species from 48 genera and 21 families of Psoco-

ptera. The majority of species (72) belong to the most advanced suborder Psocomorpha.

The present study reports data on the karyotypes of 8 species from 8 genera and 6 families of Psocomorpha. The data on *Neopsocopsis* Badonnel, 1936, *Hemineura* Tetens, 1891 and *Kolbia* Bertkau, 1882 are the first ones for these genera. For 6 species data on numbers of seminal follicles are also given.

MATERIAL AND METHODS

The material studied is listed in Table 1.

For karyological studies, the specimens were fixed in a mixture of 96% ethanol and glacial acetic acid (3:1). Testes were dissected out of the abdomens and squashed on slides in a drop of 45% acetic acid. The prepara-

tions were made permanent by a dry ice technique (Conger, Fairchild, 1953). After cover slips were removed, slides were dehydrated in fresh 3:1, air-dried and stained by Feulgen-Giemsa procedure (Grozeva, Nokkala, 1996). Slides were treated in 1N HCl at room temperature for 20 min, hydrolysed in 1N HCl at 60°C for 7 min, stained with Schiff's reagent for 30 min, rinsed in distilled water and then, rinsed in Sorensen's phosphate buffer, pH 6.8. Finally, slides were stained with 5% Giemsa solution for 30 min. After staining, slides were rinsed briefly with distilled water, air dried, and mounted in Entellan.

RESULTS

Family Caeciliusidae

Valenzuela oyamai (Enderlein, 1906): 2n = 16 + XX/X0.

Each testis contains three seminal follicles arranged in consecutive order on seminal duct. In MI, 8 autosomal bivalents and the X chromosome have been revealed (Fig. 1). The bivalents gradually decrease in size; the X chromosome is the smallest element of set. In the majority of cells, the X chromosome is situated at the periphery of the metaphase plate. The formula of the male diploid karyotype has

Table 1. Material used for chromosomal analysis.

Species	Locality, year of collection, number of specimens studied, feeding plants
<i>Valenzuela oyamai</i> (Enderlein, 1906) (Caeciliusidae)	Russia, Irkutsk Prov., Bolshie Koty, 2007, 12♂, undet. herbs
<i>Kolbia quisquiliarum</i> Bertkau, 1883 (Amphipsocidae)	Russia. Voronezh Prov., Hopersky State Reserve, 2005, 2♂, <i>Calamagrostis epigeios</i>
<i>Peripsocus golubae</i> Lienhard, 2006 (Peripsocidae)	Russia, Krasnodar Terr., 12 km N Adler, 2004, 2♂, <i>Buxus</i> sp.
<i>Trichopsocus dalii</i> (McLachlan, 1867) (Trichopsocidae)	Russia, Krasnodar Terr., 12 km N Adler, 2004, 5♂, undet. herbs
<i>Elipsocus moebiusi</i> Tetens, 1891 (Elipsocidae)	Finland, Kustavi, 2003. 4♂, deciduous trees Finland, Katanpää, 2003. 2♂, 3♀, deciduous trees Finland, Ruissalo, 2003, 3♂, 1♀, deciduous trees Russia. Voronezh Prov., Hopersky State Reserve, 2005, 1♂, 1♀, <i>Quercus</i> sp.
<i>Hemineura dispar</i> Tetens, 1891 (Elipsocidae)	Finland, vicinity of Turku, 2003, 11♂, deciduous trees
<i>Amphigerontia contaminata</i> (Stephens, 1836) (Psocidae)	Finland, vicinity of Turku, 1999, 4♂, dead coniferous branches
<i>Neopsocopsis hitricornis</i> (Reuter, 1893) (Psocidae)	Russia, republic of Altai, 40 km SE Chamal, 2006, 6♂, undet. coniferous

been determined as $2n = 17$ ($16 + X0$).

Family Amphipsocidae

Kolbia quisquiliarum Bertkau, 1883: $2n = 14 + \text{neo-XY}/\text{XX}$.

In MI, 8 bivalents have been revealed (Fig. 2). In the majority of cells, one of the bivalents is clearly heteromorphic and could be considered the sex chromosome bivalent (Fig. 3). Apparently, the X chromosome is fused with an autosome resulting in a neo-XY sex chromosome system. The formula of the male diploid karyotype has been determined as $2n = 16$ ($14 + \text{neo-XY}$).

Family Peripsocidae

Peripsocus golubae Lienhard, 2006: $2n = 16 + \text{XX}/\text{X0}$.

Each testis contains one large seminal follicle. In MI, 8 autosomal bivalents and the X chromosome have been revealed (Fig. 4). The bivalents gradually decrease in size; the X chromosome is the smallest element of the set. The formula of the male diploid karyotype has been determined as $2n = 17$ ($16 + X0$).

Family Trichopsocidae

Trichopsocus dalii (McLachlan, 1867): $2n = 16 + \text{XX}/\text{X0}$.

Each testis contains one large seminal follicle. In MI, 8 autosomal bivalents and the X chromosome have been revealed (Fig. 5). The bivalents gradually decrease in size; X chromosome is the smallest element of the set. In the majority of cells, the X chromosome is situated at the periphery of the metaphase plate. In MII homologues segregate regularly and chromosomal plates with 8 and 9 univalent chromosomes respectively, have been observed (Fig. 6). The formula of the male diploid karyotype has been determined as $2n = 17$ ($16 + X0$).

Family Elipsocidae

Elipsocus moebiusi Tetens, 1891: $2n = 12 + \text{XX}/\text{X0}$.

In MI, 6 autosomal bivalents and the X chromosome have been revealed (Fig. 7). One of the bivalents is nearly twice as large as any other. The X chromosome is close in size to smallest half-bivalents. In the majority of cells, the X chromosome is situated at the periphery of the metaphase plate. The formula of the male diploid karyotype has been determined as $2n = 13$ ($12 + X0$). A female mitotic metaphase (Fig. 8) displays 12 chromosomes with one large chromosomal pair. Sex chromosomes are not distinguished.

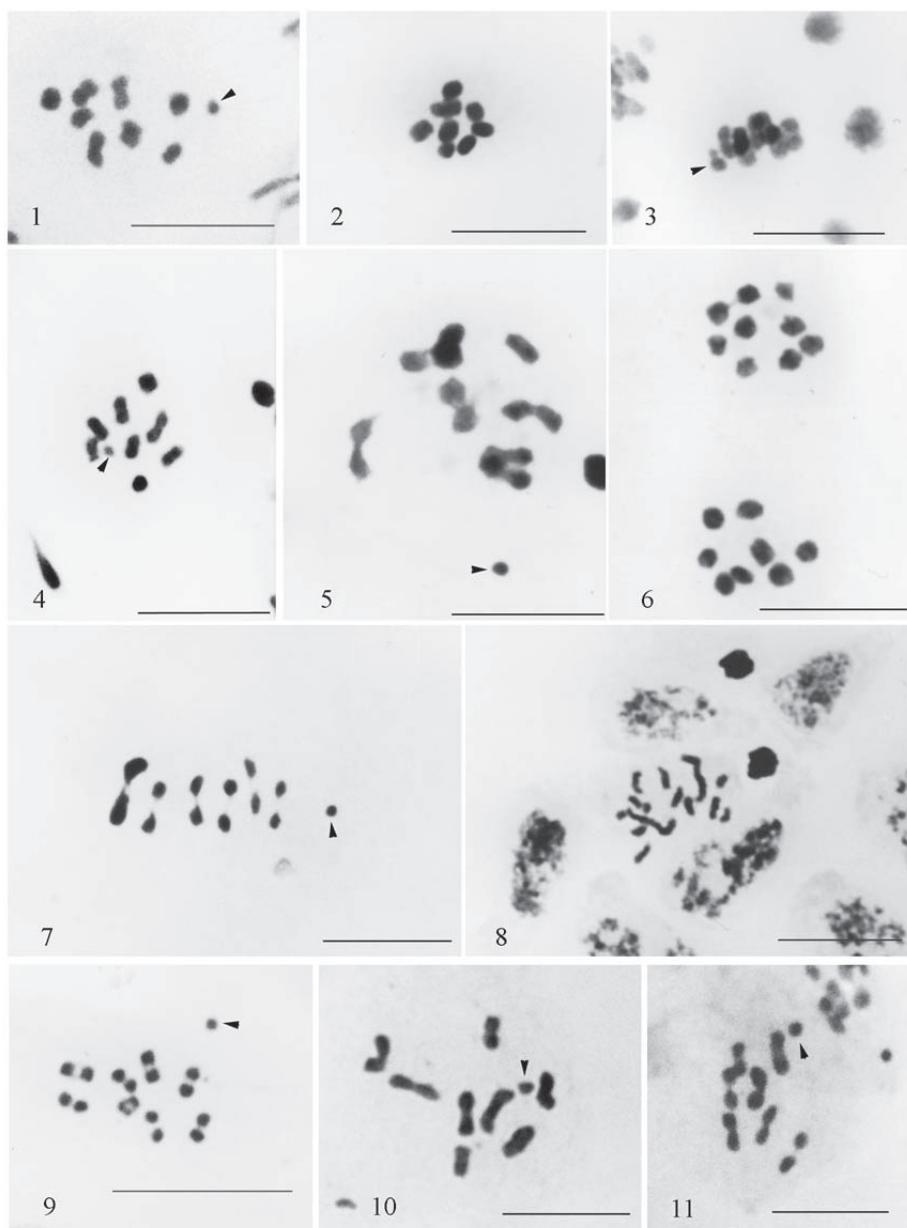

Hemineura dispar Tetens, 1891: $2n = 16 + \text{XX}/\text{X0}$.

Each testis contains three seminal follicles arranged in consecutive order on seminal duct. In MI, 8 autosomal bivalents and the X chromosome have been revealed (Fig. 9). The bivalents gradually decrease in size; the X chromosome is close in size to the middle-sized half-bivalents. In the majority of cells, the X chromosome is situated at the periphery of the metaphase plate. The formula of the male diploid karyotype has been determined as $2n = 17$ ($16 + X0$).

Family Psocidae

Amphigerontia contaminata (Stephens, 1836): $2n = 16 + \text{XX}/\text{X0}$.

Each testis contains three seminal follicles which are terminally brought together on seminal duct. In MI, 8 autosomal bivalents and the X chromosome have been revealed (Fig. 10). The bivalents gradually decrease in size; the X chromosome is close in size to the middle-sized half-bivalents. The formula of the male diploid karyotype has been determined as $2n = 17$ ($16 + X0$).

Figs 1-11. Chromosome complements of Psocomorpha. **1** - *Valenzuela oyamai*. Male meiotic metaphase I showing 8 autosomal bivalents and univalent X chromosome. **2-3** - *Kolbia quisquiliarum*. Male meiotic metaphase I showing 8 bivalents. One of the bivalents is clearly heteromorphic (better represented in Fig. 3). **4** - *Peripsocus golubae*. Male meiotic metaphase I showing 8 autosomal bivalents and univalent X chromosome. **5-6** - *Trichopscus dalii*; **5** - Male meiotic metaphase I showing 8 autosomal bivalents and univalent X chromosome; **6** - Male meiotic metaphases II showing 8 (autosomes only) and 9 (autosomes + X chromosome) elements. **7-8** - *Elipsocus moebiusi*; **7** - Male meiotic metaphase I showing 6 autosomal bivalents and univalent X chromosome; **8** - Female mitotic metaphase showing 12 chromosomes. **9** - *Hemineura dispar*. Male meiotic metaphase I showing 8 autosomal bivalents and univalent X chromosome. **10** - *Amphigerontia contaminata*. Male meiotic metaphase I showing 8 autosomal bivalents and univalent X chromosome. **11** - *Neopsocopsis hitricornis*. Male meiotic metaphase I showing 7 autosomal bivalents and univalent X chromosome. Sex chromosomes are indicated by arrowheads. Bar = 10 μ m.

Neopsocopsis hitricornis (Reuter, 1893):
 $2n = 14 + XX/X0$.

Each testis contains three seminal follicles which are terminally brought together on seminal duct. In MI, 7 autosomal bivalents and the X chromosome have been revealed (Fig. 11). One of the bivalents is noticeably larger than others. The X chromosome is close in size to the middle-sized half-bivalents. In the majority of cells, X chromosome is situated at the periphery of the metaphase plate. The formula of male diploid karyotype has been determined as $2n = 15$ ($14 + X0$).

DISCUSSION

With our new results, the karyotypes of 90 psocopteran species from 51 genera and 21 families are presently known (Table 2). The five species studied in the present work, *Valenzuela oyamai* (Caeciliusidae), *Peripsocus golubae* (Peripsocidae), *Trichopsocus dalii* (Trichopsocidae), *Hemineura dispar* (Elipsocidae), and *Amphigerontia contaminata* (Psocidae), share $2n = 16 + XX/X0$. The same chromosome complement is characteristic of 72 bisexual and diploid parthenogenetic species of Psocoptera. For triploid parthenogenetic species the chromosome number $3n = 27$ was reported (Nokkala, Golub, 2002, 2006), which number comprises 18 chromosomes of the diploid complement and one additional haploid chromosomal set. Thus, our new results confirm the high stability of chromosome numbers in Psocoptera (Wong, Thornton, 1966; Mesa et al., 1991; Golub, 1999).

Three species studied here show the deviating karyotypes. In *Elipsocus moebiusi* (Elipsocidae) $2n = 12 + XX/X0$. This chromosome number is the lowest one in Psocoptera, and previously was reported only for *Loensia variegata* Latreille, 1799 (Psocidae) (Golub, 2004). Two other studied species from the genus *Elipsocus* Hagen, 1866 are characterized

by $2n = 16 + XX/X0$ (Table 2).

Neopsocopsis hitricornis (Psocidae) was shown to have $2n = 14 + XX/X0$. These are the first karyological data on the genus as a whole. In the family Psocidae 26 species have been karyologically studied so far, among them three species also display $2n = 14 + XX/X0$ (Table 2).

Kolbia quisquiliarum (Amphipsocidae) has $2n = 14 + neo-XY/XX$, and these are the first karyological data on the genus as a whole. Previously, the neo-XY-mechanism of sex determination has been found in *Amphipsocus japonicus* Enderlein, 1906 (Amphipsocidae) (Golub, Nokkala, 2001). Although this derivative sex-determining mechanism has never been reported for any other families, karyological data are still inadequate to consider this mechanism as characteristic of the family Amphipsocidae.

The karyotype with $2n = 16 + XX/X0$ is prevalent and considered ansectral for Psocoptera, including the advanced suborder Psocomorpha (Wong, Thornton, 1966; Golub, 1999). On the basis of all karyological data available, it may be suggested that in Psocomorpha chromosome numbers tend to decrease (Table 2). Thus, the diploid chromosome number decreases from $2n = 17$ (in males of 22 species) to $2n = 15$ (in 3 species) and $2n = 13$ (one species) in the family Psocidae, as well as from $2n = 17$ (in 5 species) to $2n = 13$, (one species) in the family Elipsocidae. Both studied species of the family Amphipsocidae have $2n = 16$ and neo-XY/XX mechanism of sex determination. Only in the family Stenopsocidae the chromosome number increases from $2n = 17$ (in 3 species) to $2n = 23$ (in 2 species). Data on karyotypes in other families are restricted to 1-4 species all of which have the modal karyotype $2n = 17 + X0$. In contrast, chromosome numbers in the primitive suborder Trogiomorpha seem to show a tendency to increase. Only

<i>Atrichadenotecnum nudum</i> (Thornton, 1961)	16+XX/X0	Wong, Thornton, 1966

two species of the suborder display $2n = 17$ in males, whereas all other studied species have the higher chromosome numbers: $2n = 19, 21$ and 29 in males. Karyological data on Troctomorpha are presently extremely scanty. In four so far studied species of the suborder $2n = 14 + XX/X0$ and $2n = 16 + XX/X0$ have been found (Table 2).
