Citation: Bhowmick BK, Jha S (2022) A critical review on cytogenetics of Cucurbitaceae with updates on Indian taxa. Comparative Cytogenetics 16(2): 93–125. <https://doi.org/10.3897/compcytogen.v16.i2.79033>

Abstract

The cytogenetic relationships in the species of Cucurbitaceae are becoming immensely important to answer questions pertaining to genome evolution. Here, a simplified and updated data resource on cytogenetics of Cucurbitaceae is presented on the basis of foundational parameters (basic, zygotic and gametic chromosome numbers, ploidy, genome size, karyotype) and molecular cytogenetics. We have revised and collated our own findings on seven agriculturally important Indian cucurbit species in a comparative account with the globally published reports. Chromosome count (of around 19% species) shows nearly three-fold differences while genome size (of nearly 5% species) shows 5.84-fold differences across the species. There is no significant correlation between chromosome numbers and nuclear genome sizes. The possible trend of evolution is discussed here based on molecular cytogenetics data, especially the types and distribution of nucleolus organizer regions (NORs). The review supersedes the scopes of general chromosome databases and invites scopes for continuous updates. The offline resource serves as an exclusive toolkit for research and breeding communities across the globe and also opens scope for future establishment of web-database on Cucurbitaceae cytogenetics.

Keywords

chromosome, genome size, karyotype, NORs, ploidy

Introduction

The family Cucurbitaceae contains an extensive range of diversity consisting of about 1000 species spread over 96 genera (Renner and Schaefer 2017). The diversity of plant families is associated with variation in genome sizes and chromosome numbers as a result of enormous adaptive radiation (Soltis et al. 2004; Lysák and Schubert 2013). The viewpoint of evolution has been changed with the understanding of whole genome duplication (WGD) (Soltis et al. 2014) followed by core-eudicot hexaploidy (Wang et al. 2018). A cytogenetic database is essential to gain insights into evolution by supplementing phylogeny trees with chromosome number information (Mota et al. 2016) to upgrade knowledge on plant systematics (Soltis et al. 2014; Viruel et al. 2021). Cucurbitaceae, being the fourth most important and one of the earliest consumed vegetables yielding family, has coped with extreme climates, extensive human intervention and a huge domestication syndrome (Chomicki et al. 2020). Considerable advances have been made in molecular phylogeny (Renner and Schaefer 2016; Bellot et al. 2020; Chomicki et al. 2020; Guo et al. 2020) and genomics (CuGenDB, <http://cucurbitgenomics.org>) (Zheng et al. 2019). We had previously discussed about the gaps in cytogenetic studies (Bhowmick and Jha 2015b) which has been surmounted with the advent of molecular cytogenetics.

Currently, we have collated the cytogenetic reports of Cucurbitaceae globally and integrated our own findings for a collective interpretation. The review attempts to address i) the trend of chromosome evolution in specific tribes and species based on available information, ii) correlation between chromosome numbers and ploidy or genome size in the studied taxa and iii) the requirement of an exclusive cytogenetic catalogue for genome researchers, taxonomists and breeders working on Cucurbitaceae.

Methodological approaches

Data compilation

The data have been collated as per Schaefer and Renner (2011) after consultation of books, Chromosome atlases, research articles and public resources like Chromosome Counts Database (CCDB; <http://ccdb.tau.ac.il/>) (Rice et al. 2015), The Index to Plant Chromosome Numbers (IPCN, <http://legacy.tropicos.org/Project/IPCN>) (Goldblatt and Lowry 2011) and The Plant DNA C-values database (Pellicer and Leitch 2020) (<https://cvalues.science.kew.org/>).

Chromosome analysis in the Cucurbit species occurring in India

Presently an enzymatic maceration and air drying (EMA) method followed by fluoro-chrome banding has been employed as per our previous protocols (Bhowmick et al. 2012, 2016; Bhowmick and Jha 2015a, 2019, 2021) to represent fresh karyotypes of seven agriculturally important cucurbit species (Table 1) belonging to Benincaseae and

Sicyoee. Fresh and healthy roots were used from different sources (like germinating seeds, seedlings and underground root stocks). Roots were pretreated with 0.002 M hydroxyquinoline and fixed in 1:3 aceto-methanol solution. The standardization of EMA- fluorescence banding was conducted for the different species. In brief, fixed roots were digested in enzyme mixture [1% Cellulase (Onozuka RS), 0.75% Macerozyme (R-10), 0.15% Pectolyase (Y-23), 1 mM EDTA] for 40–45 min at 37 °C, macerated on slides, air-dried, stained with 2% Giemsa solution (Merck, Germany) and plates selected for karyotyping. After de-staining, slides were kept in McIlvaine buffer, stained with 0.1 µg mL⁻¹ DAPI for 15–20 min in darkness. For CMA staining, slides were incubated in 0.1 mg mL⁻¹ CMA for 15–25 min in darkness. For meiotic chromosomes, fixed anthers were digested in enzyme mixture for 5–8 min, macerated on slides and DAPI staining protocol was followed with minor modifications. All slides

Table 1. Chromosome numbers and nature of fluorescent bands in some cucurbit species occurring in India.

Tribes	Species (common name, status of cultivation/ wild)	Collection site, Latitude/ Longitude	Fruit image	2n	CMA bands		DAPI bands (Non-nucleolar)
					Nucleolar	Non-nucleolar	
Sicyoee	<i>Luffa acutangula</i> Linnaeus, 1753 (ridged gourd, cultivated)	Bhubaneswar, Odisha, 20.2960°N, 85.8245°E		26	11 th , 12 th , 13 th	12 th (centromeric)	1 st to 13 th (distal)
	<i>Luffa cylindrica aegyptiaca</i> Miller, 1768 (sponge gourd, cultivated)	Imphal, Manipur, 24.6637°N, 93.906°E		26	12 th , 13 th	1 st , 2 nd (distal)	0

	<i>Trichosanthes dioica</i> Roxburgh, 1832 (pointed gourd, cultivated)	Bhagalpur, Bihar, 25.2414°N, 86.9924°E		22 (female) 22 (male)	0 0	7 th , 8 th , 10 th (distal) 0	1 st to 11 th
Benincaseae	<i>Benincasa hispida</i> Thunberg, 1784 (ash gourd, cultivated)	Imphal, Manipur, 24.6637°N, 93.906°E		24	12 th	9 th (distal)	0
	<i>Coccinia grandis</i> Linnaeus, 1767 (ivy gourd, restricted cultivation)	Nagpur, Maharashtra, 21.1458°N, 79.0881°E		24 (female)	8 th , 12 th *	1 st to 5 th , 8 th to 12 th (centromeric)	0
				24 (male)	8 th , 12 th *	1 st to 5 th , 8 th , 10 th to 12 th (centromeric)	0

were mounted in non-fluorescent glycerol and chromosome plates were observed under a Zeiss Axioscop 2 fluorescence microscope (using UV and BV filter cassettes for DAPI and CMA stains, respectively). Images were captured using the attached ProgRes MFscan Jenoptik D07739 camera and ProgRes CapturePro 2.8.8 software.

Statistical analyses

Statistical analysis involving foundational cytogenetic parameters have been demonstrated to imply significant knowledge on chromosomal evolution within a group (Winterfeld et al. 2020). Considering the lack of hypotheses, we have tested for correlation between the dependent variables (2C genome size, MCL and HCL) and predictor variables [chromosome number ($2n$) and ploidy level (pI)] and also calculated linear models for regression analysis using IBM SPSS (v23, free).

The modern cytogenetic catalogue of cucurbitaceae

Along with the global review, fresh EMA based somatic plates and idiograms (Figs 1–3) of Indian species are presented here. We retain the previous designation of 10 tribes as ‘understudied’ (Bhowmick and Jha 2015b), excluding Indofevilleae, having no cytological reports.

Chromosome numbers

Currently, chromosome counts are available for 188 species (~19%) belonging to about 44 genera (~46%) of the 15 tribes, including the less attended ‘understudied tribes’. Within the ‘understudied tribes’, chromosome counts are available for only 42 species (out of almost 310) belonging to 17 genera (out of nearly 44). The basal number ranges from $x/n = 5$ (*Thladiantha* Bunge, 1833) to $x/n = 15$ (*Zanonia* Linnaeus, 1753) in these tribes (Table 2). Polyploidy has been abundantly reported in Gomphogyneae. Momordiceae have almost 60 species (Schaefer and Renner 2011) of which reports are known in nearly 11 species. The dibasic condition is noticed in *Momordica* Linnaeus, 1753 ($x = 11$ and 14) (Table 3) while polyploidy is detected in *M. charantia* Linnaeus, 1753 and *M. dioica* Willdenow, 1805 ($2n = 56$). *M. cymbalaria* Hooker, 1871, has the lowest count ($2n = 18$). In Bryonieae the X-Y sex determination system has been analysed in *Bryonia* Linnaeus, 1753 as the model along with *Ecballium* Richard, 1824 (Bhowmick and Jha 2015a). Chromosome counts are reported so far in 10 species of *Bryonia* ($x = 10$) and its sister genus *Ecballium* ($x = 12$ or $x = 9$, Table 4). Polyploidy is frequent in *Bryonia*. Sicyoae is largest in terms of species (~264–266 species) (Schaefer and Renner 2011) of which cytological reports are known in around 14% species belonging to 9 genera (Table 5). Sicyoae species range from $x = 8$ to $x = 14$ (Table 5). *Trichosanthes* Linnaeus, 1753 and *Luffa* Miller, 1754 have $x = 11$ and $x = 13$, respectively (Table 1). The less prevalent numbers include $x = 12$, $x = 8$ and $x = 9$ (Table 5). The possibility of multiple base number is noted in *Frantzia* Pittier, 1910 ($x = 12/14$) and *Sicyos* Lin-

Figure 1. naeus, 1753 ($x = 12/13/14$). Natural tetraploids are known in two species of *Trichosanthes* while the majority are diploids. Benincaseae is the second largest tribe comprising of 204–214 species in 24 genera (Schaefer and Renner 2011). Cytological reports are known in around 35% species (76 species of which 41 belong to *Cucumis* Linnaeus, 1753) of 12 genera (Tables 6, 7). $x = 12$ is the prevalent condition in Benincaseae (Tables 1, 6, 7). Dual base numbers are noted in the widely studied *Cucumis* ($x = 7, 12$). *Coccinia* Wight et Arnott, 1834 ($x = 12$) may also possess dual base numbers ($x = 10$ in *C. trilobata* Cogniaux, 1895). Molecular cytogenetics of *Cucumis sativus* Linnaeus, 1753

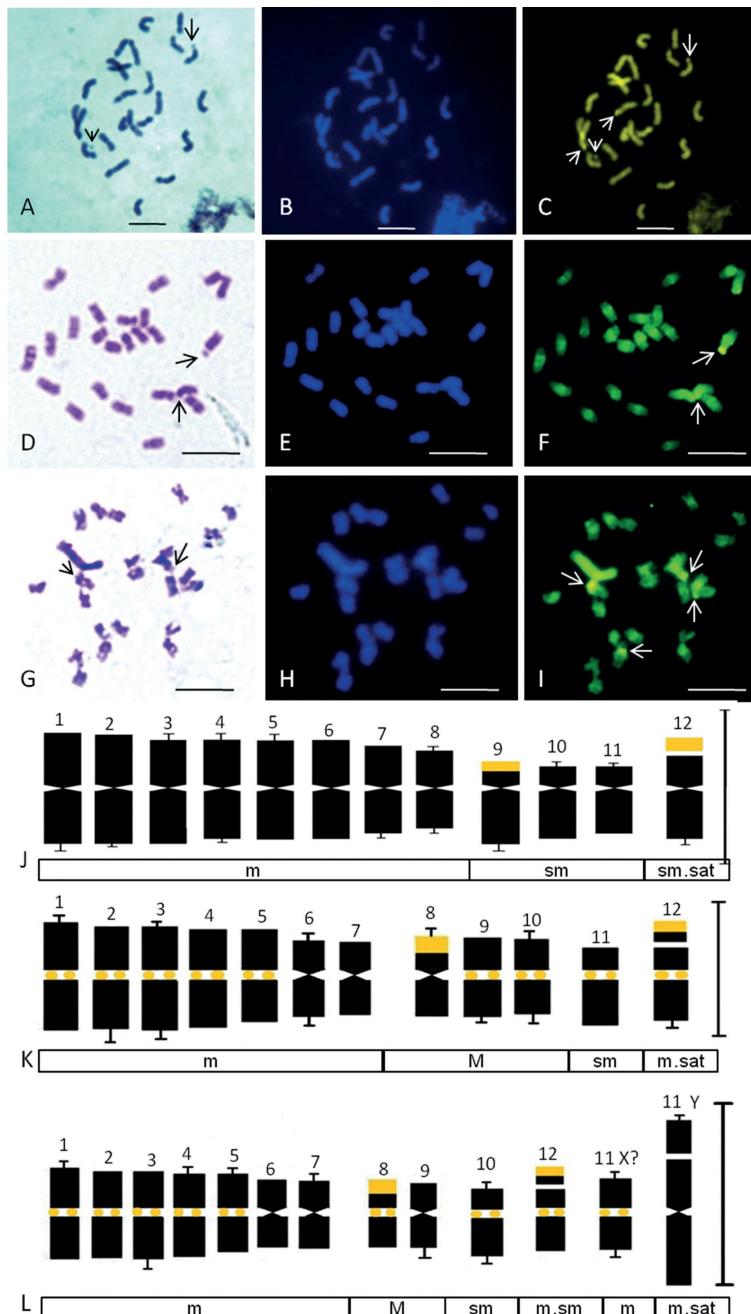

Figure 3. Somatic metaphase chromosomes and idiograms of two Benincaseae species ($2n = 24$) stained with Giemsa (**A, D, G**), DAPI (**B, E, H**) and CMA3 (**C, F, I**). **A-C** *Benincasa hispida* **D-F** *Coccinia grandis* (female plant) **G-I** *Coccinia grandis* (male plant). Arrows indicate satellites in Giemsa plates and distal CMA^{+ve} signals in **C, F, I**. Note the longest Y chromosome without any CMA band in **G-I** and centromeric CMA^{+ve} signals in **F, I**. Corresponding somatic idiograms (haploid set) of: **J** *Benincasa hispida* **K** *Coccinia grandis* (female plant) **L** *Coccinia grandis* (male plant) with CMA^{+ve} (golden yellow) bands. Note the X chromosome remaining indistinguishable in **L**. Scale Bars: 5 μ m

has demonstrated the evolution of $x = 7$ from $x = 12$ in Benincaseae. $x = 11$ has been confirmed in *Citrullus* Schrader, 1836 and *Lagenaria*. The base number of *Melothria* Linnaeus, 1753, *Solena* Loureiro, 1790 and *Zehneria* Endlicher, 1833 can be $x = 11$ or $x = 12$ or both (Table 6). Cases of natural polyploidy are noted only in four species of *Cucumis* (Table 7). Cytogenetic information is available for 17 species in three genera of Cucurbiteae with $x = 10$ and many polyploids (Table 8). The zygotic chromosome numbers of *Luffa*, *Trichosanthes*, *Benincasa* Savi, 1818 and *Coccinia*, corroborate the previous reports (Figs 1–3, Table 1).

Nuclear genome contents

Nuclear genome sizes are reported in 49 species (-5% of total species) belonging to 15 genera (-16% of total genera) of Cucurbitaceae. Among the understudied tribes, 2C genome content is known for one species each from Gomphogyneae and Coniandreae (Table 2). Within the Momordiceae species of India, significant interspecific genome size differences have been reported (Ghosh et al. 2021). The species differed 5.19-fold in their genome sizes (2C = 0.72–3.74 pg) (Table 3) (Ghosh et al. 2021). Interestingly, the species with lowest chromosome number (*M. cymbalaria*, 2n = 18) contained highest nuclear DNA content among the four *Momordica* species (Table 3). In Bryonieae, flow cytometric genome size of *Bryonia* shows a 2.2-fold increase than *Ecballium* (Table 4). In case of Sicyoae, flow cytometric 2C DNA content ranges from 1.49–2.32 pg/2C, indicating 1.55-fold differences in genome size. *Echinocystis lobata* Michaux, 1803, in spite of tetraploid condition, shows lowest genome size (Table 5). There is no significant difference in genome size between the genders of *Trichosanthes dioica* Roxburgh, 1832

Table 3. Cytogenetic information in *Momordica* (Momordicaceae) #.

2n: Zygotic chromosome number; n: gametic chromosome number.

(Table 5). Genome size estimates are known from 24 Benincaseae species of which 17 species belong to *Cucumis* (Tables 6, 7). Highest 2C nuclear genome is known in *Benincasa hispida* Thunberg, 1784 (1.97 pg) (Bhowmick and Jha 2015a) while the lowest is known in *Cucumis melo* var. *inodorus* Harz, 1885 (0.64 pg) (Karimzadeh et al. 2010). In case of *Cucumis*, there is yet no consensus on whether the taxa with different base numbers (x = 7, 12) have correspondingly dissimilar genome sizes since the researchers depended on diverse methods of genome size estimation. Lower 2C genome size was reported in *C. Coccinia grandis* Linnaeus, 1767 (2n = 24) while *C. trilobata* (2n = 20) had higher 2C DNA content (Table 6). The divergence in genome size between genders was found to be highest in dioecious *C. grandis* (Table 6), a sharp contrast to dioecious *Trichosanthes dioica* (Table 5). Benincaseae shows a 3.07-fold overall difference in genome size. Genome sizes are known in eight species of *Cucurbita* Jussieu, 1789. Flow cytometric genome size ranges from 0.686–0.933 pg/2C, indicating a 1.36-fold variation (Table 8). Despite polypoidy, the nuclear DNA content of *Cucurbita* species is comparable to many diploids.

Karyotypes, chromosome banding and molecular cytogenetics

Among the understudied tribes, information on chromosome morphology, size and karyotype are reported in very few taxa (Table 2). In *Gynostemma pentaphyllum* Thunberg, 1784, the number of rDNA loci was suggested to reduce during polyploidization (Pellerin et al. 2018). The *Actinostemma tenerum* Griffith, 1837, genome contained in-

terstitial telomeric repeats which were suggested to be the result of chromosome fusion from ancestral genome. The co-localization of 45S and 5S rDNA loci in *A. tenerum* and *Thladiantha dubia* Bunge, 1833, have been thought to imply regional synteny and shared ancestral traits (Xie et al. 2019b). In the tribe Cucurbitae, detailed karyotype analysis is known only in *Cucurbita moschata* Duchesne, 1786 and *C. pepo* Linnaeus, 1753, showing conserved 45S and 5S rDNA signals (non-co-localized) in independent analyses (Table 8).

Karyotypes and chromosome sizes are reported in ten species of Momordiceae (Table 3). Interspecific differences have been observed and found to correlate with phylogenetic

relationship within *Momordica* (Ghosh et al. 2021). Infraspecific delimitation of Indian *M. charantia* varieties was based on fluorochrome banding pattern and genome size divergence (Table 3), corresponding to infraspecific distinction reported in the Japanese bitter gourd cultivars (Kido et al. 2016). FISH in three *Momordica* species revealed 45S and 5S rDNA sites to be localised on different chromosomes (Table 3). In context of the genome sequence of bitter gourds (Matsumura et al. 2020), further scopes for cytogenetic and genomic investigation remain open.

Karyotype and chromosome size is reported in eight 8 species of Sicyoeeae (Table 5). Fluorochrome banding pattern has facilitated comparative analysis in *Luffa* species occurring in India (Tables 1, 5) (Bhowmick and Jha 2015a, 2021). The cultivated ridged gourd (*L. acutangula* Linnaeus, 1753) showed three CMA⁺ satellite bearing pairs (Fig. 1A–C, J) as in the wild *L. echinata* Roxburgh, 1814 (Fig. 1G–I, L), while the sponge gourd (*L. aegyptiaca* Miller, 1768) has two satellited pairs (Fig. 1D–F, K). *Luffa acutangula* and *L. echinata* also showed up distal DAPI bands (Fig. 1J, L), absent in *L. aegyptiaca* (Fig. 1K). *Trichosanthes* species ($2n = 22$) have inter-specific differences (Fig. 2) as well as infraspecific distinction (*T. cucumerina* Linnaeus, 1753) in fluorochrome banding pattern (Tables 1, 5, Fig. 2A–H). The male and female plants of *T. dioica* show similar chromosome number, morphology and genome size but show differences in fluorochrome banding pattern (Fig. 2I–P, Table 5). The 11th, 12th and 13th pairs (CMA⁺) are marker chromosomes in *Luffa* (Fig. 1, Table 1) while the 10th and 11th pairs are conserved CMA⁺ satellited pairs in *Trichosanthes* (Fig. 2, Table 1). Eight species of Sicyoeeae have been subjected to FISH (Table 5). The polyploid and diploid species have differences in the number of rDNA loci, showing separate localization of the 45S and 5S rDNA signals except *Sicyos angulatus* Linnaeus, 1753 and *Trichosanthes kirilowii* Maximowicz, 1859 (Table 5).

Benincaseae generally reveal two distal 45S rDNA loci of which at least one locus is either adjacent to 5S rDNA locus (Table 6) or co-localized in the same chromosome as in most of the *Cucumis* species (Table 7). Exceptionally, a wild species of *Benincasa* (*B. fistulosa* Stocks, 1851) has non-adjacent 45S and 5S signals (Li et al. 2016). GC rich satellites were observed in the 12th pair of chromosomes showing CMA⁺ bands in cultivated Indian ashgourd (*B. hispida*) (Fig. 3 A–C, J, Tables 1, 6). *Lagenaria siceraria* Molina, 1782 and *Cucumis melo* Linnaeus, 1753 are the other two genera having similarity in rDNA hybridization profile, agreeing with phylogenetic affinity (Li et al. 2016).

Citrullus colocynthis Linnaeus, 1753 and *C. lanatus* Thunberg, 1794 may share a common ancestor both having two 45S rDNA loci and one 5S locus. Loss of one 45S rDNA locus has given way to *C. rehmii* De Winter, 1990 while gain of one 5S rDNA locus has been proposed to lead to *C. ecirrhosus* Cogniaux, 1888 and *C. lanatus* var. *citroides* Bailey, 1930 (presently *C. amarus* Schrader, 1836) (Reddy et al. 2013; Li et al. 2016). GISH using *C. lanatus* var. *citroides* genome has revealed divergence from *C. lanatus* var. *lanatus* (Reddy et al. 2013).

The genus *Cucumis* is the largest in Benincaseae with 65 species of which 39 have been studied (Table 7). Among the *Cucumis* species with $x = 12$, co-localization rDNA loci (45S and 5S rDNA) have been documented in 14 species, including *C. melo* (Table 7). However, the number of 45S sites is generally four, which may be six or eight in some

cases (Table 7). rDNA hybridization data strongly corroborated with the ‘fusion’ theory for derivation of $x = 7$ (*C. sativus*) from $x = 12$ (*C. melo*) (Waminal and Kim 2012) which is substantiated by genomic studies (Li et al. 2011). There are ten pericentromeric/ centromeric 45S and two distal 5S rDNA sites in *C. sativus* while six 45S rDNA sites were reported in *C. sativus* var. *hardwickii* Royle, 1835 (Koo et al. 2005; Zhang et al. 2012). Comparative chromosome painting (Lou et al. 2014) and GISH (Zhang et al. 2015) proved high colinearity between cucumber and melon. Based on chloroplast and nuclear DNA (ITS) phylogeny, *C. melo* (melon) has been found to be sister to a clade comprising *C. sativus* and related genera (*Dicaelospermum* Clarke, 1879 and *Mukia* Arnott, 1840) (Renner et al. 2007). rDNA site co-localization was found to coincide with geographical origin of 12 *Cucumis* species (Zhang et al. 2016). The chromosomal affinity between *C. metuliferus* Schrader, 1838, *C. anguira* Linnaeus, 1753, *C. zeyheri* Sonder, 1862, *C. myriocarpus* Naudin, 1859 and polyploid *C. heptadactylis* Naudin, 1859 (dioecious) (Yagi et al. 2015) can be substantiated by their phylogenetic proximity based on chloroplast and nuclear DNA (ITS) sequences (Renner et al. 2007). rDNA distribution of *C. metuliferus* was also the reason to consider proximity with *Citrullus naudinianus* Sonder, 1862, (previously *Acanthosicyos naudinianus* Sonder, 1862) (Reddy et al. 2013). Infraspecific differences were documented in *Cucumis melo* on the basis of 45S- 5S rDNA signals (linked or separated) which also possessed unique centromeric satellites (Setiawan et al. 2018, 2020). Moreover, chromosome painting method elucidated chromosomal rearrangement in some *Cucumis* species (Lou et al. 2014; Li et al. 2018).

The dramatic evolution of Y chromosome was validated in karyotypes (Fig. 3 D–I, K–L) of *Coccinia grandis* (Table 6). The 45S rDNA sites enabled confirmation of NORs in the 8th and 12th pair containing distal GC rich CMA⁺ signals in *C. grandis* (Fig. 3 D–I, K–L, Tables 1, 6). 45S and 5S rDNA hybridization pattern was similar in three other *Coccinia* species and *Diplocyclos palmatus* Linnaeus, 1753 (Table 6). The three closely related dioecious species of *Coccinia* accumulated Y chromosome repeats and displayed sex chromosome turnover (Sousa et al. 2017). Strong centromeric CMA bands (Fig. 3 D–I, K–L, Table 1) were observed in *C. grandis* except Y chromosome (Fig. 3 I, L), presenting a possibility that *CgCent* (CL1) is a feature of centromeres of dioecious *Coccinia* species (Sousa et al. 2017). In addition, non-nucleolar CMA⁺ heterochromatin might be associated with sexual differentiation of autosomes in dioecious *C. grandis* (Fig. 3) which is also a marker in *Trichosanthes dioica* (Fig. 2, Table 1), opening good scope for further study.

Distinct 45S rDNA sites are higher in number than 5S rDNA sites in Cucurbitaceae (Fig. 4) (Waminal and Kim 2012). The distal 45S rDNA loci are conserved genomic landmarks (Fig. 4) while 5S rDNA loci are relatively diverse (Fig. 4). Based on the literature reports, some NORs (Type I) included chromosomes showing non-colocalized 45S and 5S rDNA sites in seven species of Benincaseae, one species each from Cucurbitae and Momordiceae and two species of Sicyoae. The rearrangement of 45S rDNA site in *Cucumis sativus*, probes for chromosome number reduction which may be a consequence of diploidization. The second type (Type II) shows colocalised 45S and 5S rDNA loci, either adjacent or distant, but always on the same chromosome and found in one species each of Benincaseae, Sicyoae and Actinostemmateae. The third type (Type III) was characterized by chromosomes with non-colocalized and

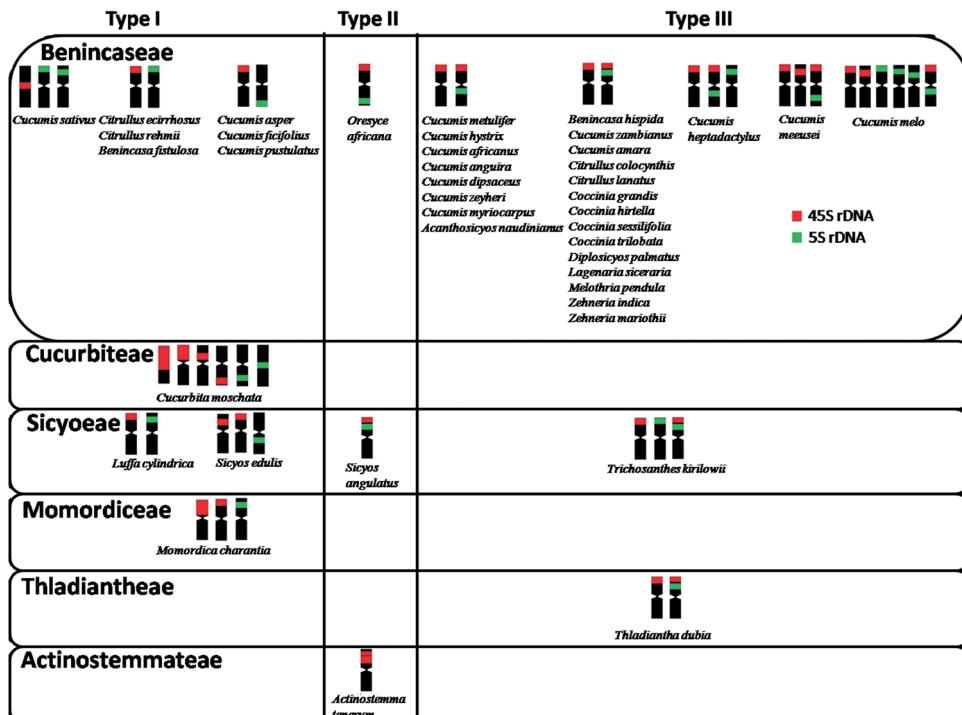

Figure 4. Types of chromosomes bearing the NORs as per available reports of rDNA hybridization in Cucurbitaceae. Type I: Chromosomes with only non-colocalised 45S and 5S rDNA sites, Type II: Chromosomes with colocalised 45S and 5S rDNA sites, Type III: Chromosomes with both non- and colocalised 45S and 5S rDNA sites. See text for explanation.

colocalised 45S and 5S rDNA loci, as in 14 species of Benincaseae and one species each of Sicyoae and Thladiantheae. The rDNA sites of majority of *Cucumis* species were of non-adjacent type. Hence, type III NORs in majority of Benincaseae genera advocates conservation of the marker chromosomes having distal NOR (45S rDNA). *Gynostemma pentaphyllum* and some polyploid *Cucumis* reveal rDNA loci reduction after polyploidization (Zhang et al. 2016; Pellerin et al. 2018).

Correlation between parameters

Chromosome numbers in Cucurbitaceae range from $x = 5$ to $x = 16$. The most prevalent number $x = 12$ (Fig. 5) is considered ancestral (Xie et al. 2019b), followed by $x = 11$, 13, 14 and 10 (Fig. 5). The present regression analyses for 41 taxa (including 16 Indian taxa) (Table 9) revealed significant linear correlation between $2n$ and HCL, between ploidy and genome size and between ploidy and HCL (Fig. 6). Therefore, an increase in ploidy/ $2n$ number is linked with increase in HCL. There was no significant correlation between 2C genome size and chromosome numbers. Cytogenetic parameters may not reflect residual evidence of CCT in Cucurbitaceae at present, as reasoned by Alix et al. (2017).

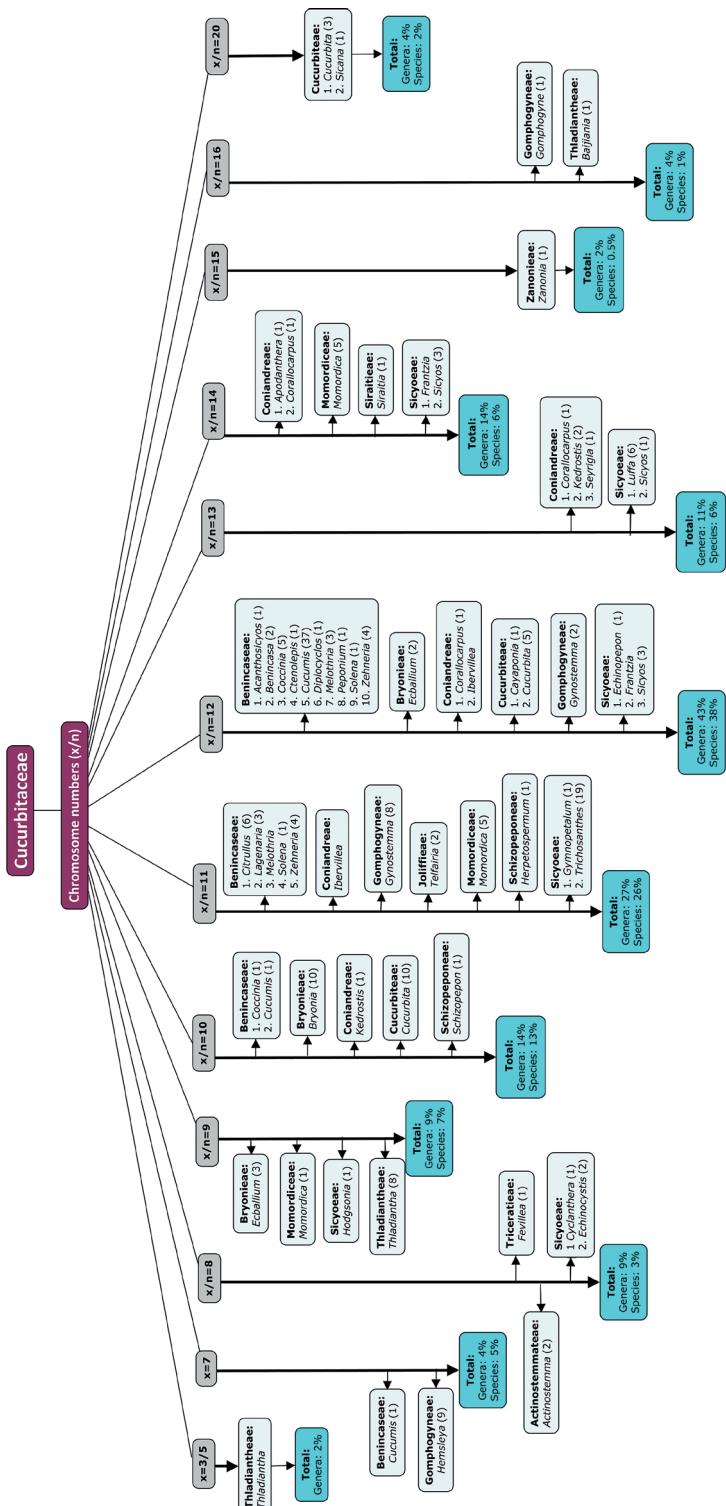

Figure 5. The types of different base numbers (x , based on published reports) or possible base numbers (x/n , based on reported haploid counts) in Cucurbitaceae. The numbers in brackets beside names of genera signify the number of species whose chromosome counts are reported. The % of genera and species with a particular chromosomal number is indicated at the end arrow (out of a total of 44 genera and 188 species with chromosome counts).

Table 9. Data on fundamental cytogenetic parameters utilized for statistical analysis.

calculated from chromosome measurements reported in publications, ## different entries for same taxa were taken from different reports

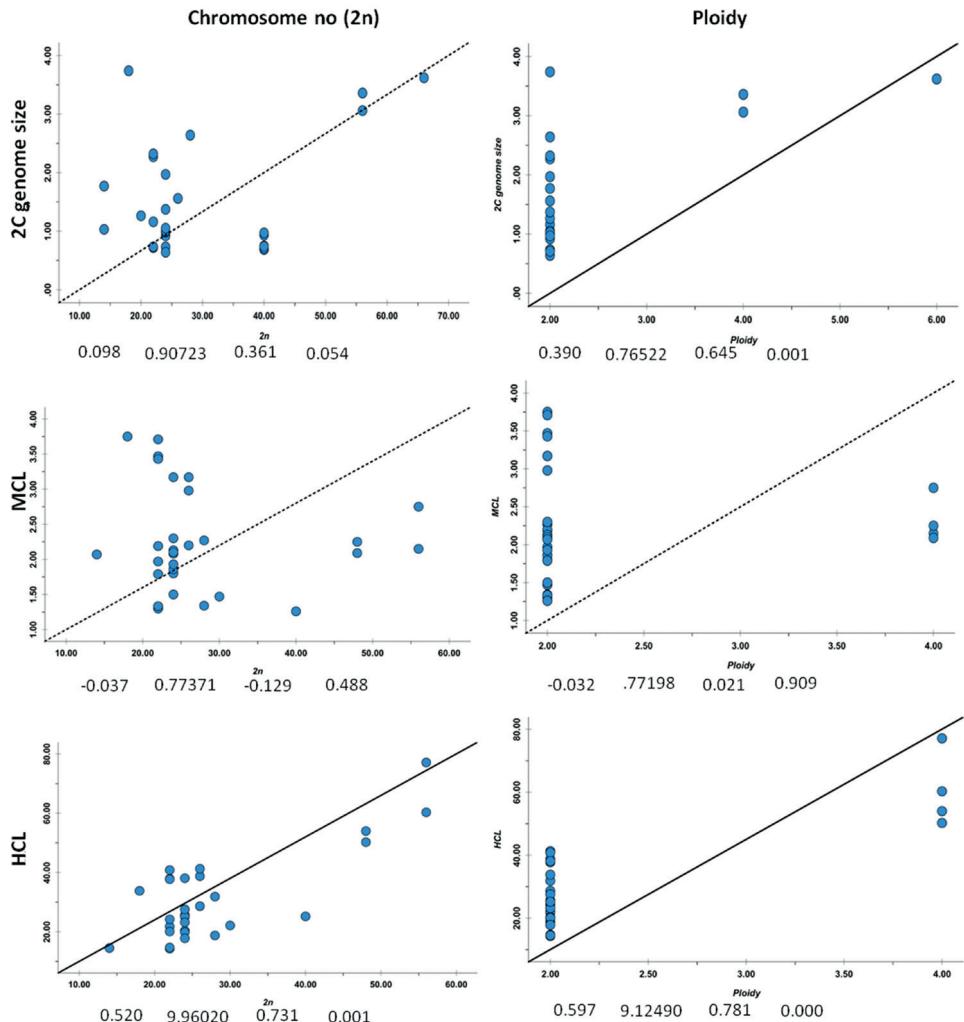

Figure 6. Scatter plots of $2n$ chromosome number and ploidy level (predictor variables) versus $2C$ genome size, MCL (mean chromosome length) and HCL (total length of haploid chromosome set) in Cucurbitaceae taxa. Symbols below plots depict regression analysis parameters; square: adjusted R square, circle: standard error of the estimate, triangle: Pearson Correlation, star: 2-tailed significance of Pearson Correlation. Regular lines indicate significant linear regression and dotted lines indicate not significant linear regress.

Future directions

Chromosome number and genome size information in the basal clades (understudied tribes) should be given attention to infer ancient base numbers. The parameters of fundamental and molecular cytogenetics are inevitable for genomic interpretation (Weiss-Schneeweiss and Schneeweiss 2013; Deakin et al. 2019) and hence relevant to spot genetic resources and relationships with wild relatives. The current review is not exhaustive but supersedes the scopes of general web resources and brings an offline resource exclusive for Cucurbitaceae.
